

PUGET SOUND VITAL SIGNS

INDICATOR NUMBER OF NATURAL-ORIGIN CHINOOK SALMON ON SPAWNING GROUNDS

This indicator evaluates the abundance values and their trends of the 22 Chinook salmon populations from five Puget Sound regions as measured by the number of natural-origin adult fish on the spawning grounds. Abundance estimates here do not include hatchery-origin fish (with few exceptions) or Chinook taken in harvest or by predators like orcas. The indicator is intended to reflect the goal of achieving wild population recovery of Puget Sound Chinook, which are federally listed as threatened.

Indicator
Progress

Target
Status

Target

By 2050, all Chinook salmon populations increase, and at least 50 percent of the populations reach their recovery goals.

Key Vital Sign Indicator Results

- There is little to no sign of recovery of Puget Sound Chinook populations in each biogeographic region. On the other hand, no populations have decreased significantly in abundance since the time Chinook salmon were listed as threatened under the Endangered Species Act in 1999. Therefore, our conclusion about progress of the populations of Puget Sound Chinook salmon is “No Trend.”
- Estimates of population spawner abundance of the 22 Puget Sound Chinook populations have changed very little since the baseline reference period when the populations were listed in 1999.
- While most populations remain far below their recovery planning targets adopted by NOAA Fisheries, some are doing better (see the [indicator map](#)). For instance, the recent 5-year abundance geomean for Suiattle River spring Chinook salmon is greater than its low productivity planning target for abundance. Upper Sauk River spring Chinook salmon and Upper Skagit River summer Chinook salmon are at 45% and 36%, respectively, of their low productivity planning targets.
- The Puget Sound Partnership recently set a recovery target for all Chinook salmon populations to increase and at least half of the populations to reach their recovery goals by 2050.
